+3.3V LVDS Receiver 24-Bit Flat Panel Display (FPD) Link - 85 MHz, +3.3V LVDS Receiver 18-Bit Flat Panel Display (FPD) Link - 85 MHz

General Description

The DS90CF386 receiver converts the four LVDS data streams (Up to 2.38 Gbps throughput or 297.5 Megabytes/sec bandwidth) back into parallel 28 bits of CMOS/TTL data (24 bits of RGB and 4 bits of Hsync, Vsync, DE and CNTL). Also available is the DS90CF366 that converts the three LVDS data streams (Up to 1.78 Gbps throughput or 223 Megabytes/sec bandwidth) back into parallel 21 bits of CMOS/TTL data (18 bits of RGB and 3 bits of Hsync, Vsync and DE). Both Receivers' outputs are Falling edge strobe. A Rising edge or Falling edge strobe transmitter (DS90C385/DS90C365) will interoperate with a Falling edge strobe Receiver without any translation logic.

The DS90CF386 is also offered in a 64 ball, 0.8mm fine pitch ball grid array (FBGA) package which provides a 44 % reduction in PCB footprint compared to the 56L TSSOP package.

This chipset is an ideal means to solve EMI and cable size problems associated with wide, high speed TTL interfaces.

Features

- 20 to 85 MHz shift clock support
- Rx power consumption <142 mW (typ) @85MHz Grayscale
- Rx Power-down mode <1.44 mW (max)
- ESD rating >7 kV (HBM), >700V (EIAJ)
- Supports VGA, SVGA, XGA and Single Pixel SXGA.
- PLL requires no external components
- Compatible with TIA/EIA-644 LVDS standard
- Low profile 56-lead or 48-lead TSSOP package
- DS90CF386 also available in a 64 ball, 0.8mm fine pitch ball grid array (FBGA) package

Note 4: Receiver Skew Margin is defined as the valid data sampling region at the receiver inputs. This margin takes into account the transmitter pulse positions (min and max) and the receiver input setup and hold time (internal data sampling window - RSPos). This margin allows for LVDS interconnect skew, inter-symbol interference (both dependent on type/length of cable), and clock jitter (less than 150 ps).

Applications Information

POWER SEQUENCING AND POWERDOWN MODE

Outputs of the transmitter remain in TRI-STATE until the power supply reaches 2V. Clock and data outputs will begin to toggle 10 ms after V_{CC} has reached 3V and the Powerdown pin is above 1.5V. Either device may be placed into a power-down mode at any time by asserting the Powerdown pin (active low). Total power dissipation for each device will decrease to 5 μW (typical).

The transmitter input clock may be applied prior to powering up and enabling the transmitter. The transmitter input clock may also be applied after power up; however, the use of the PWR DOWN pin is required as described in the Transmitter Input Clock section. Do not power up and enable (PWR

DOWN = HIGH) the transmitter without a valid clock signal applied to the TxCLK IN pin.

The FPD Link chipset is designed to protect itself from accidental loss of power to either the transmitter or receiver. If power to the transmit board is lost, the receiver clocks (input and output) stop. The data outputs (RxOUT) retain the states they were in when the clocks stopped. When the receiver board loses power, the receiver inputs are controlled by a failsafe bias circuitry. The LVDS inputs are High-Z during initial power on and power off conditions. Current is limited (5 mA per input) by the fixed current mode drivers, thus avoiding the potential for latchup when powering the device.
